Before the next challenge.

My name

George Arbache

A question I want to resolve

What is the best way to use Unity to create a 3D bounty hunting video game with player movement, interactive characters, bounty missions, and a storyline? What programming skills and tools should I learn first to build a playable version of my game?

Recall. Question. Recalibrate.

What have I completed?

I have completed research and planning for my bounty hunting video game. I developed the main game concept, planned the storyline, created ideas for bounty missions, and researched Unity and its features. I also learned about how Unity uses objects, components, and C# scripts to create gameplay. My previous research notes and project plans will help guide the development of my game. I still need to continue building and testing the playable version.

My explanation of classes, objects, data and actions

In Unity, classes are used to create objects and control how they behave. For example, I can create a PlayerController class for my bounty hunter character. The object will have data such as health, movement speed, and money. It will also have actions such as moving, interacting with objects, and accepting missions. A C# script can control these actions. When the player presses the movement keys, the character moves around the 3D environment. This connects programming code to something the player can see on the screen.

My questions, answers and remaining uncertainty

One question I still have is how to create a complete bounty hunting mission system in Unity. I understand that C# scripts can control characters and objects, but I still need to learn how to connect missions, rewards, and different objectives together. I plan to research Unity tutorials, read the official documentation, and practice writing C# scripts. I can also ask my instructor or classmates for help when I encounter problems.

My personal GitHub repository URL

https://github.com/DemonicAssets/Week-11-Repository

Readiness check

I have completed my research and planning for my bounty hunting video game. I have organized my project ideas, storyline, Unity research, and C# programming notes. I plan to use Unity to develop and test my game and GitHub to save and organize my project files. I will make sure my work is saved, commit my changes, and push my files to my personal GitHub repository. I will also open my GitHub link to verify that my repository is accessible and my files are available. My next goal is to continue developing the game and create a playable bounty hunting mission.

Replace Chapters with Pipelines

Attention First, Chapter 3, pp. 37–41 (132-page edition).

What I understand from this chapter

This chapter explains the different pipelines, and how the different hats mean different things, for example the visual hat is when the person is thinking for ideas, and the logic hat means the person is connecting the data, and the integrity.

My opinion and reasons

I agree with the three pipelines, and that you should never rush because if you rush then it leads to errors so always do the beginning first don't skip it.

A decision I can apply

The Bounty app is the characters are in the application, which is a game to catch the bad guys that stole dogs. It matters because we want our app to be working, and functional. We are preparing to turn it from an application to a video game.

A question or next investigation

How do we attract the fans?
How we know which hat to wear?

Design for the Attention Economy

Attention First, Chapter 6, pp. 53–58 (132-page edition).

What I understand from this chapter

Chapter 6 argues that attention is not a gift from the learner. It is something a design has to earn. The book says a learning experience is competing against "optimized entertainment" like games and streaming, not against boredom (p. 53). It also says attention works at four thresholds: 5 seconds, 5 minutes, 5 hours and 5 years (p. 54). Its main idea is attention leakage: unclear directions, dead openings, random transitions and busy work quietly drain focus (p. 54). Split-attention can be intrinsic, like stress, hunger or fear of looking foolish, or extrinsic, like cluttered visuals, too many instructions and unnecessary screen switching. The book says extrinsic leaks are usually preventable and should be redesigned (p. 55). It also warns about "attention debt," where forcing compliance makes the next session cost more (p. 57).

My opinion and reasons

I agree that when people drift, the system should be checked before blaming their discipline (p. 54). In a bounty hunting game, if players skip the tutorial or quit during a hunt, the usual cause is that they can't tell what the target is, why it matters or what to do next. I would qualify the idea that more engagement is always better. The book says the answer is sometimes fewer screens and more silence (p. 56). A hunting game needs quiet stretches like tracking, waiting and reading clues, so too much stimulation could work against the tension. Example for your game: [a specific moment, such as a cluttered HUD during a chase or a bounty board with too many contracts at once].

A decision I can apply

Attention leak: In my previous work, [your real example, e.g. a team project or game where players or teammates had too many things on screen or unclear next steps]. This matches the "Overloaded interface: I cannot tell what matters" leak, whose fix is to reduce clutter and raise contrast (p. 55).

Design change: In the game's interface, I would show only the current bounty's target, location clue and reward during a hunt, and move the map, inventory and other contracts into a menu the player opens on purpose. I would also show a visible "next node" for the hunt (track, confront, capture), which answers the "No visible progress" leak (p. 55).

How I'll notice it helps: I'll watch a few playtesters for 5 minutes without helping. If they can say what their goal is without asking, stop checking menus mid-hunt and finish the first bounty, it's working. If they look checked out or keep asking "what do I do?", the leak is still there (p. 56).

A question or next investigation

How can a game tell the difference between productive tension and attention leakage, like deliberate silence while tracking a target versus a player who is just lost? A specific point to test: whether removing the minimap during the first bounty changes how long players stay engaged (the 5-minute “hook” threshold on p. 54).

Two notes. The “Reading lens and team connection” dropdown in your screenshot is collapsed, so if it asks you to connect to a specific team scenario, tell me what it says and I’ll adjust the drafts. Also, since your instructor wants it “in your own words,” treat these as scaffolding and rewrite them in your voice.

Identity and the Creator Loop

Attention First, Chapter 7, pp. 61–69 (132-page edition).

What I understand from this chapter

Chapter 7 defines identity as stabilization: what's left when behavior becomes consistent and repeated enough that it describes you better than your intentions do (p. 61). The book says that if a system can't survive the end of excitement, it has "rented enthusiasm" instead of building identity (p. 61). It also argues that people see the "paint" (the visible pattern, like confidence or humor) but not the "canvas" underneath that shapes it (pp. 62–65). For creators, it offers the First-Fan Principle: protect the quality of what you build, and notice where the story breaks and the standard slips (p. 66). It adds the Lore Protocol, which means defining the values that survive when the room gets tired and making your standards visible enough to protect (p. 66). Finally, it says failure is structural to success (p. 67) and that principles steer where rules break (pp. 68–69).

My opinion and reasons

I agree that identity comes from repeated behavior, not announcements, and that a creator should be their own first fan. For my game, that means the "lore" (what bounty hunters in this world believe, protect and refuse) should drive design decisions when I'm tired or tempted to cut corners. I'd qualify the idea that frustration always means you've found your growth edge (p. 68). Sometimes frustration is a sign of a bad process, like unclear tasks or no visible progress, and that needs a system fix instead of just pushing through. Work example: [a specific moment from your project, such as a feature you shipped that didn't fit the game's tone, or a time you skipped a standard because you were tired].

A decision I can apply

Past artifact or mistake: [your real one, e.g. a bounty mission, prototype or asset you rushed that didn't match the world you wanted]. My response showed that I was treating it like "an assignment I hoped to finish" instead of "a world I'm responsible for maintaining" (p. 66).

Standard I'll protect: Every bounty, character and mechanic must fit the game's lore: what hunters value, what they refuse to do, and what the world costs them.

Small repeatable action: At the end of each work session, I'll check one finished piece against a short lore checklist (three questions: Does it fit our values? Does it make the world more coherent? Would I be proud to show it?) and fix or cut what fails. This follows "treat repeated behavior as identity votes" and "build standards that still work on tired days" (p. 69).

A question or next investigation

How small can a “survivable node” be before it stops proving anything (p. 68)? A specific point to test: whether finishing one small, complete bounty mission each week builds more momentum than working on larger features for several weeks without shipping anything (the principle “let small completions prove big claims,” p. 69).

As before, the “Reading lens and team connection” dropdown is collapsed in your screenshot. If it asks for a specific team angle, tell me what it says and I’ll adjust. And since the prompt wants your own words and your own past mistake, fill in the italic parts with your real example and reword the rest in your voice.

Designing Your Teams and Tools

Attention First, Chapter 8, pp. 71–74 (132-page edition).

What I understand from this chapter

Chapter 8 says a learning or creation environment should be built around a mission, not around objects or authority. Its "tool and temple" idea is that tools are not the point. The temple, meaning the thing the tools protect and help create, like the quality of the work or the mission of the team, is the point (pp. 71–72). The "Hammer Problem" warns that owning a great tool doesn't help if the mission is unclear, because it only speeds up the confusion (p. 72). The chapter separates a tool, which offers reliable utility, from a team member, which changes how you think, perceive, decide or create. The same object, even a whiteboard or AI, can be either depending on the relationship (p. 72). It also contrasts Masters, who protect craft and ask "Is this excellent?", with Chiefs, who protect direction and ask "Is this aligned, survivable, and worth it?" (p. 72). Finally, the Hierarchy of Creative Autonomy says that as AI becomes infrastructure, human work shifts from manual labor toward judgment, specs, boundaries, lore and mission (p. 73).

My opinion and reasons

I agree that the mission should come before the tools. For my bounty hunting game, picking an engine, art tool or AI assistant because it's familiar is the Hammer Problem if I haven't first said what the game needs. I like the tool-versus-team-member distinction, because it makes me ask what a tool actually contributes. I'd qualify the idea that every object should become a "teammate." Some tools should stay simple utilities, like a file backup or a version-control system, and making them more complicated would add attention leaks. Work example: [a tool you chose mainly because it was familiar or popular, and how it helped or got in the way].

A decision I can apply

Mission and missing capability: The mission is a bounty hunting game with a coherent world and satisfying hunts. The capability I'm missing is [e.g. art, level design, audio, programming, or balancing].

What I can contribute: [your real strength, e.g. game design, story, or systems].

Tool with a justified purpose: [a specific tool] because it covers [the missing capability], not just because I already know it. I'll keep it a tool if it only executes a narrow task. If it helps me iterate, challenge assumptions or see patterns I'd miss (like AI helping balance bounty difficulty), I'll treat it as a team member and review its output (p. 72).

Craft vs. direction: Protecting craft (Master) means polishing one hunt mechanic until it's excellent. Coordinating direction (Chief) means deciding which features are worth building and keeping the game coherent. At this stage I'll mostly wear the Chief hat, because the project needs alignment before polish.

When I switch to Master, I'll know which hat is on before I start (p. 73).

Responsibility I'll accept: I'll own the game's mission and lore, and I'll review anything a tool or teammate produces against them (Level 4–5 on p. 73).

A question or next investigation

How do I tell when a tool has crossed from "tool" to "team member" on a project like this? A specific point to test is the Sidekick Test from p. 74: after a week of using [the book], does it help me think better, return to the work and notice more, or does it only store information?

The Human Operating System

Attention First, Chapter 11, pp. 93–103 (132-page edition).

What I understand from this chapter

Chapter 11 argues that we're moving from an age of static knowledge to one of "dynamic orchestration," where information is abundant and tools are active, so the key question is how a human operates inside that environment (p. 93). A healthy "human operating system" needs both the child, who explores and asks reckless questions, and the adult, who sequences, budgets and verifies (p. 94). The "Leaf in the River" says intelligence is speed, but wisdom is knowing which current is carrying you somewhere worth going (p. 94). The chapter says "human-as-tool" is no longer enough, because the human advantage is orchestration, meaning, taste and directing systems toward worthwhile ends, like a conductor (p. 96). It also says ADD and P2P work at both a macro scale (teams, programs, life direction) and a micro scale (a prompt, a screen, a next step) (pp. 97–98). Finally, it warns against two extremes: strict control produces "human robots," and unlimited freedom produces "undefined humans." The "Bowl Problem" is throwing random things in a bowl and still having to eat the result (p. 101).

My opinion and reasons

I agree that creators need both the child and the adult. For my bounty hunting game, the child is trying odd mechanics, like a hunt that works by tracking sounds instead of a map. The adult is deciding what's scoped, tested and actually shippable. I also agree that speed isn't direction, because AI and tools let me generate assets or code fast, but that doesn't tell me whether the game is going somewhere worth going (p. 94). I'd qualify the chapter's claim that institutions are "decades behind" and its long list of future technologies. That part is speculative, and the core point about judgment and balance holds up better without it (pp. 99–100). Work example: [a time you built something fast with a tool but later realized it didn't fit the game, or a time you got stuck planning and never tried anything].

A decision I can apply

Mission worth my effort: Build a bounty hunting game with a coherent world and satisfying hunts, and finish a playable version of it.

Alternative I considered: [e.g. a larger open-world game, or a different genre that felt easier to finish]. I chose this mission because [your real reason, e.g. it's scoped small enough to finish and I care about its theme].

What I'll explore freely: Unusual hunt mechanics, target personalities, and art or sound direction. This is the child side, so I'll experiment without worrying yet about polish.

What I'll verify: Whether each feature fits the game's lore and mission, whether anything a tool or AI

generates is accurate and works, and whether a playtester can finish a hunt without my help. This is the adult side, and it avoids the Bowl Problem (p. 101).

When I'll reconsider: At the end of each milestone (for example, after the first complete bounty is playable), I'll check whether the mission still fits or needs to be narrowed.

A question or next investigation

How do I know when exploring freely has turned into drifting? A specific point to test: for two weeks, try each new idea in a small time-boxed experiment (the child) and then check it against a short list of lore and scope questions (the adult), and see how many ideas survive.

Bring something to the summit.

The connection across the readings

The readings helped me understand the importance of having a clear purpose, working with other people, paying attention to details, and using the right tools to accomplish a goal. I can apply these ideas to my bounty hunting video game by creating a story with meaningful missions, interesting characters, and challenges that require players to think carefully. I want my game to have more than just bounty hunting. I want players to experience a world with different characters, choices, objectives, and consequences.

Evidence I am ready to show

A prospective teammate can inspect my game's story, character ideas, mission concepts, world design, and research. I can show how the game will work, what players will be able to do, and how the different missions connect to the overall storyline. I still need to learn more about Unity, game mechanics, character animations, 3D modeling, and programming so I can turn my ideas into a playable game.

My board in words

My whiteboard represents how all the parts of my bounty hunting video game connect. The story is at the center because it gives the game its purpose. The main character takes on bounty hunting missions, meets different characters, explores different locations, and makes decisions throughout the game. Each mission connects to the larger storyline. The characters, locations, weapons, equipment, and technology all help build the game world. Unity will be the main development tool used to bring these ideas together and create the final gaming experience.

Choose where you want to go.

My direction

Join a lead

The mission I want to explore

I want to create a bounty hunting video game where players take on missions to track down wanted criminals, explore different locations, and complete objectives. The game is for people who enjoy action, adventure, exploration, and story-driven games. One story moment that can become playable is when the main character receives a bounty, investigates the target, follows clues, and completes the mission.

My pitch

My purpose is to create an entertaining bounty hunting video game with an interesting storyline and exciting missions. I bring the main game concept, story ideas, mission designs, and research about Unity. I have already started developing ideas for the characters, environments, and gameplay. I need help with programming, 3D modeling, animations, sound design, and creating missions. My next step is to continue learning Unity and develop a playable version of my game.

Conversations and decisions

I want to work with people who are interested in video game development and have different skills that can help bring my project to life. I learned that creating a video game takes teamwork, communication, planning, and creativity. Some people may be better at programming, while others may understand character design, storytelling, or 3D modeling. My goal is to find people who can contribute their skills while learning new things together. We will work toward creating a playable bounty hunting game.

Agree on the work.

How the literature strengthens this team

The readings taught me that having a clear purpose and working together as a team are important when creating a successful project. One insight is that everyone should understand the main goal. This will help my team stay focused on creating a bounty hunting game with an interesting storyline and missions. Another insight is that communication and learning from others can improve the final product. I will use these ideas by dividing responsibilities between programming, character design, 3D modeling, animations, and storytelling. Everyone will have a role in helping develop the game.

Communication and check-in plan

All project files, research, notes, and updates will be organized in the team GitHub repository. We can use GitHub to share progress and keep track of changes. Team members will communicate through online messages and check in once a week to discuss what they have completed, problems they are experiencing, and what needs to be improved. We will compare our results regularly to make sure everyone is working toward the same goal and that the game is developing properly.

Team GitHub URL, or Working solo

https://github.com/DemonicAssets/Week-11-Repository

Make the Attention Accord.

Purpose and smallest playable result

The purpose of my game is to allow players to experience what it is like to be a bounty hunter. The player will receive a bounty mission, search for a wanted target, follow clues, and complete the mission. The smallest playable result will be one character, one map, one bounty target, and one mission. Once the player completes the mission, they will receive a reward and see their progress change.

My attention promise

My main focus is making sure the bounty hunting missions are interesting and understandable. I will pay attention to the mission objectives, character movements, gameplay, and how the player completes each bounty. I will capture evidence through screenshots, gameplay recordings, and progress updates. This evidence will help my team understand what is working and what needs improvement.

Time and dependency plan

My first action is to create the main character and begin designing the first mission. Next, I will need a map, character models, animations, and basic programming in Unity. I will work on the project step by step and check my progress regularly. If I get stuck with programming or designing, I will research tutorials or ask teammates for help. My goal is to build a small playable mission before expanding the game.

Board explanation and contributors

My board shows how the different parts of my bounty hunting game connect. The main character receives a bounty, travels to a location, searches for the target, and completes the mission. Each action leads to a consequence, such as earning money, unlocking another mission, or progressing through the story. Contributors can help with programming, 3D modeling, character design, animations, sound effects, and storytelling. Unity will bring all these parts together to create the game.

Translate the mission into code.

My story-to-code map

The main object in my game is the Bounty Hunter Player. I will create a PlayerController component using C# in Unity. It will have properties such as player health, movement speed, current bounty, and money earned. Its methods will allow the player to move, interact with objects, and complete missions. Unity events such as Update() will check player movement, while trigger events such as OnTriggerEnter() will detect when the player enters a mission area. The visible result will be that the player can explore the map, interact with mission objects, and complete bounty objectives.

What I am borrowing and why

I will use Unity's built-in Character Controller and Input System to help create player movement and controls. I will use C# scripts to program the game's characters, missions, and interactions. The Character Controller is a Unity built-in component that helps characters move around the 3D environment and interact with the world. I will use Unity's official documentation to learn how these features work and give credit to the Unity developers. These tools will help me create a playable bounty hunting game without having to build every system from scratch.

Object lifetime and responsibility

When the game starts, Unity creates the player, environment, mission objects, and other characters. Each object will have its own responsibility. The player controls movement and interactions, while mission objects track bounty objectives and rewards. When a mission is completed, temporary mission objects can be removed or reused for another mission. I will check that objects work correctly by testing the game in Unity, checking the Console for errors, and making sure the missions can start and finish properly.

Make one moment playable.

What I expect to happen

When the player presses the WASD keys or arrow keys, the bounty hunter character will move around the game environment. When the player approaches a bounty mission board and presses the interaction key, a mission will appear on the screen. The player will be able to accept the mission, and the game will display the bounty objective. This will show that player input creates an action and produces a visible result.

What I built and where it lives

My project is a 3D bounty hunting game prototype created in Unity. The main scene contains the player character, the environment, and an object the player can interact with. The PlayerController script will control character movement, while the MissionInteraction script will handle interactions with the bounty board. I will save screenshots and gameplay recordings to show the character moving and interacting with the mission board.

A difficulty and my response

One difficulty I may encounter is getting the player movement and interaction systems to work correctly. The character might not move properly, or the interaction button might not respond. I will investigate the problem by checking my C# scripts, Unity Inspector settings, and Console errors. I will make changes to the code and test the game again. My goal is to make sure the player can move around, interact with objects, and see the results of their actions.

Test what you are claiming.

My test record

I tested the player movement to make sure the bounty hunter could move around the environment using the keyboard. I expected the character to move smoothly and respond to the controls. I also tested interacting with the bounty board when standing outside its interaction range and expected nothing to happen. When standing close to the board, I expected the mission information to appear. I also tested pressing the interaction button multiple times to make sure the mission did not activate incorrectly. I will use screenshots and gameplay recordings as evidence of my tests.

My improvement experiment

I predict that improving the interaction distance and adding a message when the player is close to the bounty board will make the game easier to understand. I plan to adjust the interaction range and add an on-screen message telling the player to press E to accept a bounty. This should make interactions clearer and prevent players from having difficulty finding out how to start missions. I will test the changes to see if they improve the gameplay experience.

Promised versus returned evidence

I planned to demonstrate player movement, interaction with the bounty board, and the ability to activate a mission. My evidence will include screenshots, gameplay recordings, and testing results. The main improvement is making the controls and mission interactions easier for players to understand. The next step for my game is to improve the mission system, add bounty targets, create more environments, and develop additional missions for players to complete.

Return with work you can explain.

My final access and file check

I will make sure my bounty hunting game project, final report, whiteboard images, and testing evidence are saved in my personal GitHub repository. I will check that all files are included, organized, and accessible. I will also review my project notes, screenshots, and gameplay evidence before uploading everything. Finally, I will test my GitHub links to make sure they work correctly and that my project is ready for my instructor to review.

My next decision

After completing this mission, I want to continue developing my bounty hunting video game by improving the player movement, adding more bounty missions, creating new characters, and designing different environments. I also want to learn more about Unity, 3D modeling, animations, and C# programming. My next goal is to create a more complete playable game with a storyline, mission progression, rewards, and different challenges for players.

Handoff

Commit and push your own project, notes, report, boards and tests. Verify file/image/link access. Include your team GitHub link if teamed. Submit one personal GitHub URL in your own Canvas record.
